ABSTRACT

Bovine cysticercosis is considered to be a dangerous problem for both public health and the livestock economy. The present study aimed to determine the cysticercus bovis prevalence and their economic losses in slaughtered cattle in Menofia governorate. Visual meat inspection of 2640 cattle carcasses at different abattoirs of Menofia governorate was carried out all over one year extended from January 2015 to December 2015. The results revealed that, the prevalence of cysticercus bovis in slaughtered cattle was 6.09% and the affected organs were head (masseter and tongue), heart and whole carcass with an infection rate of 3.63%, 2.42% and 0.04% respectively. Moreover, the morphological description and measurements of recovered cysticercus bovis were recorded. It was observed that, the cysticercosis causes sever economic losses, as the estimated annual financial losses of cysticercosis in slaughtered cattle were $7032 Egyptian Pound (EGP).

1. INTRODUCTION

Cysticercosis in cattle is a food borne disease caused by Taenia saginata with humans as the final host and cattle as the intermediate host. Infection of human by Taenia saginata occurs through ingestion of raw or undercooked meat containing cysticercus bovis. While, infection of cattle with cysticercus bovis occurs through ingestion of Taenia saginata eggs (Dupuy et al., 2014). Cysticercus bovis is the metacestode of beef tapeworm (Taenia saginata). Adult Taenia saginata measured 30 meter long and found in human small intestine (Gracey et al.,1999) which pass daily millions of eggs that resist adverse environmental conditions (Urquhart et al.1988). Lesions caused by bovine cysticercosis may be confused with Sarcocystis (Ogunremi et al.2004). Bovine cysticercosis is a worldwide distributed disease and is considered to be a dangerous problem for the livestock economy and public health, common in different countries of Africa, reaching a level of 33% in Kenya, 80% in Ethiopia and 8% in Sudan (Urquhart et al., 2007). Annual losses in Africa due to cysticercus bovis were $1.8 billion (Harrison 1996). the prevalence of cysticercus bovis ranges between 0.01 and 6.8% in various European countries (SCVPH 2000) according to meat inspection, the occurrence of Cysticercus bovis in cattle slaughtered in Croatian abattoir by physical inspection all over 5 years and recorded that their infection rate was 0.11% (Zdolec et al., 2012), but the expected prevalence is to be between three and ten times higher because of the poor efficiency of the visual detection of cyst at meat inspection (Onyango-Abuge et al.1996; Dorny et al.2000). Economic losses in the meat industry due to cysticercosis are closely related to the infection degree. In generalized cysticercosis; the carcass must be condemned totally. While, condemnation of the infected parts in localized cysticercosis must be applied. In addition to, the carcass should be stored at a temperature not exceeding −7°C for a period of 3 weeks for keeping the parasites inactivate (Gracey et al. 1999). So the aim of this study is to determine the prevalence of cysticercus bovis and their economic losses in slaughtered cattle in Menofia governorate.

2. MATERIAL AND METHODS

2.1. Study period and area
The study was carried out allover one year extended from January 2015 to December 2015 at different abattoirs of Menofia governorate (Ashmoun, El Shouhada and Shebein El Kom abattoirs) to determine the prevalence of cysticercus bovis and their economic impact in slaughtered cattle.
2.2. Recovery and examination of *Cysticercus bovis*

The present study was conducted on 2640 cattle of different sexes and ages.

The whole carcasses of 2640 adult slaughtered cattle were physically inspected for the presence of *cysticercus bovis*. The recovered Cysts from each infected carcass were collected in separate container, washed in normal saline, examined macroscopically for viability to determine viable or dead cyst. The live *cysticercus bovis* was slightly pressed between 2 glass slides and fixed in 10% formalin for microscopical examination. The samples were stained with Mayer's carmalum stain and mounted (MAFF 1986).

These cysts were identified according (Soulsby 1986; Urquhart et al.1988)

2.3. Estimation of economic losses

The economic loss due to organ condemnation was calculated according to the following equation:

\[
EL = N \times P \times W
\]

Where,
- \( EL \): Economic losses;
- \( N \): Number of condemned organs;
- \( P \): Average organ price (EGP/kg);
- \( W \): Average organ weight (kg)

3. RESULTS

3.1. Prevalence of *cysticercus bovis*

The results in table (1) showed the prevalence of *Cysticercus bovis* of slaughtered cattle at different abattoirs of Menofia governorate. Meat inspection of slaughtered cattle indicated that 161 out of 2640 (6.09%) had *Cysticercus bovis*. Concerning the locality, 80 out of 1320 examined cattle were infected with *Cysticercus bovis* at Ashmoun abattoir. While, 43 out of 720 and 38 out of 600 inspected carcasses were infected with *Cysticercus bovis* at El Shouhada and Shebein El Kom abattoirs with an infection rate of 5.97% and 6.33 % respectively. Regarding to the infected organs, 96 heads out of 2640 examined cattle were infected with *Cysticercus bovis* with an infection rate 3.63% (48 Ashmoun, 23 El Shouhada and 25 Shebein El Kom). In addition, 64 hearts out of 2640 cattle were cysticercosis infected with infection rate of 2.42% (32 Ashmoun, 20 El Shouhada and 12 Shebein El Kom). Total condemnation was carried out in one carcass with a rate of 0.04% (1 out of 2640). The total condemned carcass was reported in Shebein El Kom abattoir with an infection rate of 0.16% of the examined cattle.

The seasonal prevalence of *Cysticercus bovis* was recorded that the highest infection rates were 15.38 % in spring season followed by 13.04% in autumn season. While the lowest infection with cysticercosis was 4.85% in winter season Figure (1).

3.2. **Morphological description and Measurements of *cysticercus bovis***

Morphological description of the collected *cysticercus bovis* was recorded. Macroscopical and microscopical examination of the collected *cysticercus bovis* was reported. A Viable *cysticercus bovis* was white fluid filled cyst containing protoscolex, these cysts were measured 3.50x5.50-6.00x10.50 (4.75x8.00) mm. while, the protoscolices were 1.50x1.70-1.60x2.00 (1.55x1.85) mm. in addition, each Scolex contained 4 suckers. Each sucker was measured 0.20x0.25-0.24x0.29 (0.22x0.27) mm. the dead *cysticercus bovis* was calcified with casedated content. These measurements were reported in Table (2) and their morphology was showed in Figure 2.

90% of recovered *cysticercus bovis* were dead cysts while 10% of recovered cyst was viable cysts. All recovered viable *cysticercus bovis* were recovered from heads of examined carcasses.

3.3. Economic losses of cysticercus bovis in slaughtered cattle

The annual total economic losses from condemned parts that infected with *cysticercus bovis* in slaughtered cattle were 87032 EGP. Moreover, the economic losses from condemned heads were 63960 EGP while, the losses were 7072 EGP from condemned hearts annually. Furthermore, the economic losses from condemned one whole carcass were 16000 EGP. So the condemned heads represented 74% from total losses, then whole carcass 18%, followed by hearts 8% respectively. The highest economic losses were recorded from condemnation of the heads Table (3) and Figure (3).

4. DISCUSSION

The present study is carried out on 2640 slaughtered cattle to determine the prevalence of *cysticercus bovis* and their economic losses in Menofia province. The study concluded that the infection rate of *cysticercus bovis* was 6.09 %. The highest infection rate of *cysticercus bovis* was recorded during spring season (15.38%) and the peak of infection was observed during March (24.56%). Higher infection rate of 54 % was recorded by (Kambarage et al., 1995) in Tanzania. While, Lower infection rates were recorded by (Zivkovic et al., 1996) in Slovenia and (Zdolec et al., 2012) which were 0.78%, and 0.11% respectively. The variation in the infection rate of *Cysticercus bovis* may be due to the variation in localities, age, number and breed of the examined animals.

The Morphological description and measurements of *cysticercus bovis* was agreed with (Soulsby 1986).

The annual losses form condemned head, heart and whole carcass were 63960, 7072 and 16000 EGP respectively. These results agreed with (Efrem et al., 2015) who reported 1.5 million USD losses due to cysticercosis annually. 74% from total losses due to cysticercosis were from the condemnation of infected heads, while, the condemned hearts represented 8%. The highest economic losses were recorded from condemnation of the heads the variation in estimated losses may be attributed to variation in prevalence and localities of abattoirs.

5. ACKNOWLEDGEMENTS
Authors would like to thank faculty of veterinary medicine, Sadat City University. Also great thanks for veterinarians and workers at different abattoirs of Menofia governorate.
