Abstract

This study aimed to evaluate the potent antitumor activity of metabolites from Streptomyces as antitumor activity using in vitro and in vivo studies. The Streptomyces were purely isolated from the soil samples, re-cultured and processed to obtain their extracts. Twenty Streptomyces extracts were obtained. Two isolates of Streptomyces were characterized morphologically, physiologically, biochemically and 16s rRNA and they named Streptomyces strain Ag18 and Streptomyces strain Ag20. Twenty four female albino mice were used in the present study. The mice were divided into 4 groups (6 animals each). The 1st was control, injected subcutaneously with an isotonic saline solution. The 2nd, injected subcutaneously with Ehrlich ascites tumor cells (EAC). Both the 3rd and 4th group were injected subcutaneously with Ehrlich ascites tumor cells (EAC) diluted with an isotonic saline solution (SS); after tumor formation, (7-10) days after inoculation with EAC cells, animals were locally injected subcutaneously with Streptomyces extract, Ag18 and Ag20. The results revealed that only two of the twenty Streptomyces extracts (Ag18 and Ag20) showed their potent antitumor activity against Ehrlich ascites carcinoma cells in vitro. AG18 and AG20 Streptomyces extracts also modulated the mice body weight towards the normal values significantly (p< 0.001) and reduced the tumor volume with a very highly significant change (p< 0.001). The histological study confirmed the above mentioned result, where the kidney and liver of the mice injected with EAC returned to their normal structure after injection with Streptomyces extracts.

We concluded from this study that the bioactive product of Streptomyces Ag18 & Ag20 have antitumor activity.

Keywords: EAC (Ehrlich Ascites Carcinoma) cells, histological studies, in vitro & in vivo studies, mice, Streptomyces Ag18 & Ag20.

1 Introduction

Streptomyces are filamentous Gram-positive bacteria belonging to the phylum Actinobacteria that represents one of the largest taxonomic units among the 18 major lineages currently recognized within the domain Bacteria (Ventura et al., 2007). Actinobacteria are widely distributed in terrestrial and aquatic ecosystems, especially in soil. They are important in soil biodegradation and humus formation by the recycling of nutrients associated with recalcitrant polymers such as keratin, lignocelluloses and chitin (Goodfellow and Williams, 1983; Stach and Bull, 2005) and produce several volatile substances like geosmin responsible of the characteristic “wet earth odor” (Wilkins, 1996). They also exhibit diverse physiological and metabolic properties, such as the production of extracellular enzymes (McCarthy and Williams, 1992; Schrepmpf, 2001). Recently drug discovery from streptomycetes by using high-throughput screening and fermentation, have attracted great attention. In addition, in the last years the isolation of marine streptomycetes has been a great source of new compounds, especially antitumor substances (Bernan et al., 2004). Most of the cancer chemotherapy drugs have undesirable side effects, for that increase the demand for
novel antitumor drugs (Demain and Davies, 1999). A great number of antitumor compounds are natural products or their derivatives, mainly produced by microorganisms. The antitumor antibiotics produced by Streptomyces are invaluable in the medical field (Mueller and Nicole 2002; Azambuja et al., 2005). Lam et al., (1990) and Leet et al., (1990) recorded that Himastatin which is an antibiotic isolated from fermentation broths of *Streptomyces hygroscopicus*; had an antimicrobial activity against gram positive bacteria and was cytotoxic to mammalian tumor cell lines *in vitro*. L-Asparaginase is the first enzyme produced from Streptomyces had an antitumor activity intensively studied in human beings (Savitri and Azmi, 2003). It is used for the treatment of malignancies of the multiorgans (Kumar and Selvam, 2011). It is used widely as a therapeutic agent for treating acute lymphoblastic leukemia in children and lymphosarcoma (Khamma et al., 2009). There are few literatures on the effect of Streptomyces on tumor cells. So that the present study aimed to study the antitumor effect of Streptomyces extracts *in vitro* and *in vivo* against Ehrlich Ascites carcinoma (EAC) cells.

2 Materials and Methods

Soil sampling sites and isolation of Streptomyces

Soil samples were collected from various locations of the Tamalay village, Menoufia Governorate, Egypt from 2008 to 2009; samples were randomly collected on sites at a distance of 2 km apart from each other within the accessible areas. Soil samples (2 g per site) were randomly collected from the open land, and under the shrubs and trees. Soil samples were taken from the top (7.5 - 10 cm) of the soil profile using a sterile sample collection corer, put in sterile soil sample bags and kept in a box for transportation to the laboratory, where they were subsequently stored at 4°C.

The soil was pretreated with CaCO₃ (10:1 w/w) and incubated at 37°C for 4 days. It was then suspended in sterile Ringer solution (1/4 strength). Test tubes containing a 10-2 dilution of the samples were placed in a water bath at 45°C for 16 h; so that the spores would separate from the vegetative cells and the dilutions were inoculated on the surface of the Actinomycete isolation Agar plates. The plates were incubated at 28°C until the sporulation of Streptomyces colonies occurred. Streptomyces colonies (where the mycelium remained intact and the aerial mycelium and long spore chains were abundant) were then removed and transferred to the Yeast Extract-Malt Extract Agar (ISP2) slants. Pure cultures were obtained from selected colonies for repeated sub culturing. The isolated Streptomyces strains were maintained as suspensions of spores and mycelial fragments in 10% glycerol (v/v) at 20°C in the Genetic Engineering and Biotechnology Institute (GEBRI).

Streptomyces cultivation media composition and extracts

Antibiotic Medium was used for the cultivation of the test Streptomyces and has the following composition: [Yeast extract 5 g/l, Ammonium sulphate 0.5 g/l, Glucose 10 g/l, Peptone 10 g/l, Sodium chloride 10 g/l, and Agar 25.0 g/l]. These media were prepared according to the manufacturer instructions.

The maximum secretion of metabolites from the strain was found at the 14th day of incubation in yeast extract sucrose agar (alkaline pH 8.6) medium at 37.5°C by maintaining all the physicochemical factors at optimum level for the culture. The extraction of the metabolites was carried out by ethyl acetate on the basis of best solubility and maximum antimicrobial activities. The solvent; ethyl acetate was evaporated using a rotary evaporator at 40°C under reduced pressure. On average; 1L of culture filtrate gave 2.5 mg of crude extract.

Characterization of the isolates

Streptomyces colonies were characterized morphologically and physiologically following the directions given for the International Streptomyces Project (ISP) (Shirling and Gottlieb, 1966). General morphology was determined using the Oatmeal Agar plates, incubated in the dark at 28°C for 21 days and then by direct light microscopy examination of the surface of the cross-hatched cultures. Colors were determined according to the scale adopted by Prauser (1964). Melanin reactions were detected by growing the isolates on Peptone-Yeast Extract-Iron Agar (ISP 6) (Shirling and Gottlieb, 1966). All strains were cultivated on an ISP 2 medium. Some diagnostic characters of highly active Streptomyces strains were determined following the directions given in the *Berger's Manual of Systematic Bacteriology*.

Morphological Characterization

Streptomyces colonies on glycerol-nitrate-casein agar were transferred onto oatmeal agar and streaked across the plate and incubated in the dark at 27°C for 21 days. The criteria are investigated as follows:

**Color Determination:** this made for: a) Mass color or mature, sporulating aerial surface growth, b) The color of substrate mycelium as viewed from the reverse side, and c) Diffusible soluble pigments other than melanin. Observation was made after 21 days and was limited to mature cultures with heavy spore mass surface using code for determining the color of aerial mycelium of Streptomyceses composing by Prauser (1964) for color tabs of Baumann Farbronkarte Atlas.

**Morphology of Spore Bearing Hyphae:** the spore-bearing hyphae characteristics were determined by direct microscopic examination of the culture surface (21 days old) on opened dishes of the cross hatched cultures using 1000 X magnification. The species involved in the genus Streptomyces divide into sections: Rectus (R) or straight, flexible (F) or flexeous, Retinaculum-Apertura (RA) and spiral (S).

**Physiological Characterization:** The criteria which
investigated are as follows: Melanin Production; Peptone iron agar was used for the detection of deep brown to black diffusible pigment (+); absence of the color was recorded as negative (-). Carbon Utilization; the following sugars were tested, L-arabinose, D-xylene, meso-inositol, D-mannitol, D-fructose, rhamnose, raffinose and sucrose. Preparation was done as described in the ISP (Shirling and Gottlieb, 1966). Characterization of Streptomyces sp. strain AG18 and AG20 to species level was based on morphological, cultural and physiological characteristics following the directions given for the International Streptomyces project (ISP) (Shirling and Gottlieb, 1966).

General morphology was determined on oatmeal agar plates, incubated in the dark at 27°C for 21 days, by direct light microscopy examination of the surface of crosshatched cultures. Colors were determined according to the scale adopted by: Prauser (1964) and melanin reactions were detected by growing the isolate on at least one of the following sugars (hyperdiploidsubline) was obtained from the National Institute of Cancer, Cairo University, Egypt, and has been propagated in our laboratory by weekly intraperitoneal (IP) inoculation of about 3×10⁶ cells/mouse. Then, the ascites tumor cells obtained from donor mouse was diluted with saline solution (SS) and the viable EAC cells were counted with hemocytometer (Trypan blue indicator) under the microscope and were adjusted at 3×10⁶ EAC cells/ml. Ascitic tumor cell counts were found to be more than 99% viable by the Trypan blue dye exclusion method. For induction of solid tumors; subcutaneous injection of 3×10⁶ EAC cells per mouse was performed.

In vitro study
Cytotoxicity assay of Streptomyces extraction on Ehrlich ascites tumor cells and cell viability test were measured microscopically by calculating the viability of tumor cells. The optimal concentration of the bacterial extracts was estimated (Ag18 and Ag20). The viability percentage of tumor cells was measured after incubation with the tested extracts. According to (El-Merzabani et al., 1979); with some required modifications, the viability percentage of tumor cells were measured after incubation with the examined extracts (Ag18 and Ag20). A suspension of the tumor cells was attained from peritoneal cavities of tumor-bearing mice and then diluted twice with buffered saline solution (pH 7). In a set of sterile Eppendorf tubes; three sterile Eppendorf tubes; each containing 50μl of the diluted cell preparation was prepared; then add 150μl buffered saline solution in the first tube (control); 150μl of Ag18 was added to the diluted EAC cells in the second tube. Finally, 150μl of Ag20 was added to the prepared cell in the third tube. The three tubes were incubated in water bath at 38°C for 20 minutes. From each of the three tubes; 50μl of cell suspension was added to 50μl trypan blue and mixed in a new clean, dry and sterile Eppendorf tube, and then the number of living cells was calculated using a hemocytometer slide. Survival cells appeared as unstained bodies while non-viable cells stained blue. The percentage of cytotoxicity was calculated using the formula, Percentage of cytotoxicity = 100 – Tc-Dc/Tcx 100, where Tc= total EAC cells, and Dc = dead EAC cells.

In vivo study
The antitumor efficacy of Streptomyces extractions (Ag18 &Ag20) was investigated in vivo on mice bearing solid tumors. A total of 24 female Swiss mice were divided into 4groups (six mice per group). Solid tumor was induced in all groups of study, except normal control group, by inoculation of mice with 3×10⁶ EAC cells subcutaneously using female albino mice in their right thigh; the transplanted cells usually produce palpable tumors within a week. The volumes of the tumors of individual mouse were determined by measuring the length, width and depth of the tumors with a Vernier caliper according to the method of Papadopoulos et al., (1989).

Grouping of animals
The 24 female mice were divided randomly into 4 groups (6 animals per group):

**Group I:** Normal control - mice received sterile saline solution twice a week; through the subcutaneous injection;

**Group II:** Tumor untreated - mice were inoculated subcutaneously with 3x10^6 EAC cells and leave without injection for one month;

**Group III:** Ag18 extract - mice were inoculated subcutaneously with 3x10^6 EAC cells then injected subcutaneously with Ag18 extract after solid tumor formation (7-10) days after tumor inoculation; at the site of tumor genesis; twice a week for one month.

**Group IV:** Ag20 extract - mice were inoculated subcutaneously with 3x10^6 EAC cells then injected subcutaneously with Ag20 extract after solid tumor formation (7-10) days after tumor inoculation; at the site of tumor genesis; twice a week for one month.

**Body weight**

The tumor weight of each mouse related to the four groups was recorded from the beginning of the experiment till one month. The weights were calculated as Mean±SD and the correlation between different groups was calculated using statistical analysis.

**Solid Tumor Volume**

Tumor was induced by injecting EAC cells (3x10^6 cells/mouse) subcutaneously to the right hind limb of the mice for the groups (II, III and IV). The radii of the tumor were measured using Vernier caliper at 5 days intervals for one month starting with 15th day. The volume of the tumor was calculated using the formula \( V=\frac{4}{3}\pi r_1^2r \), where ‘r1’ and ‘r’ represent the major and minor diameter respectively (Atiaa and Weiss, 1966). This was compared with tumor untreated (Group II).

**Histological studies**

For histological examination small samples were collected from the kidney and liver from each mouse of all groups, just after scarification of mice. All specimens were fixed in 10% neutral formalin, then processed for paraffin sections (5-7 microns) and stained with Harris’s haematoxylin and eosin (H&E) according to Drury and Wallington (1980). Photomicrographs were taken using binocular digital microscope (Leica DMLB®) with 3.2 mega pixels digital camera (Leica EC3) and program software (LASEZ. 1.6).

**Statistical analysis:**

Statistical analysis was done using the Student’s t test (Murray, 1982). Comparison of mean values of studied variables among different groups was done using ANOVA test. \( P < 0.05 \) was considered to be significant.

**3 Results**

**Isolation**

There was a high diversity of Streptomyces isolates in soils from a village of Menoufia Province – Egypt. Under the shrubs and trees; rhizosphere of plants, agricultural soil and preserved areas. Pure isolates grew well on the differential agar media forming well isolated colonies. The isolates obtained formed tough, leathery and filamentous colonies that were hard to pick from the culture media, as a characteristic of actinomycetes and also produced colored pigments; which were secreted into the culture media within a few days of incubation. Twenty (20) isolates from actinomycetes were obtained but only two isolates of Streptomyces have antitumor activity (Figs.1-4).

PCR amplification of PKS and NRPS-genes

Bacterial type I (modular) PKS gene fragments were amplified with the degenerate primers KSMAF and KSMB-R, which can be used to amplify β-ketoacyl synthase (KS) domain encoding fragments of ca 700 bp. PCR with these primers resulted in amplification of fragments of expected size from Streptomyces isolates, indicating their potential for production of polyketide secondary metabolites. Since PKS type I genes encode modular enzymes, and actinomycete strains usually contain more than one PKS gene cluster, it was expected that PCR products obtained with the KS-specific primers would represent mixtures of the KS-coding sequences. Therefore, sequencing of these gene fragments would be required for a better understanding of the diversity within the selected group of isolates and their de-replication.

In vitro antitumor activity of Ag18 & Ag20 on EAC:

The Ehrlich ascites carcinoma cells appear bright (not colored) and intact in fig (6a); the viability of EAC was very high (Tumor-Untreated). On the other hand, in fig (6b), Ehrlich ascites carcinoma cells treated with Ag18 appears to be colored with trypan blue. This is also shown in case of Ag20 fig (6c). Animals bearing EAC cells treated with Ag18 and Ag20 showed a significant decrease in the total viable EAC cell count in comparison to non-treated tumor bearing animals.

In vivo antitumor activity of Ag18 & Ag20 on solid tumors:

1- Mice body weight:

The mice weights were different according to the group which is belonging to; the mice of tumor untreated group recorded elevated weights when compared to normal control, Ag18 and Ag20 groups. Streptomyces extracts (Ag18 & Ag20) reduced the weights of mice of the tumor untreated group in a very highly significant change (p < 0.001) towards the normal weights. This is obvious in Table 2.

2- Tumor size:

In relation to the measurements of tumor size of the tumor untreated, tumor treated with Ag18 and tumor treated with Ag20 groups, the recorded data showed that the Streptomyces extracts (Ag18 & Ag20) reduced the tumor volume in a very highly significant way (p < 0.001). This effect is clear in (Table 3).

3- Histological results:

Control Group

Kidney: Kidney of control animals formed of renal cortex and renal medulla. The renal corpuscles as well as proximal and distal convoluted tubules were normal. The glomerular capsule appeared normal with prominent glomerular space (Fig. 7).

Liver: Control animals showed the normal structure of liver. The liver architecture formed from polygonal lobules. The outlines of the lobules were indistinct. The hepatocytes were arranged in cords that radiated out from the center of each lobule where the central vein situated. The hepatocytes were polyhedral in shape, had vesicular spherical nuclei with prominent nucleoli and eosinophilic cytoplasm. Between these hepatic cords were the hepatic sinusoids (Fig.8). The portal area appeared normal and contained portal vein, hepatic artery and branch of bile duct.

Group II: Mice injected subcutaneously with EAC cells

Kidney: The histological structure of kidney in general showed prominent cloudy swelling of the renal tubules. The renal corpuscles appeared congested with indistinct very narrow glomerular space. Both proximal and distal convoluted tubules showed cloudy swelling and very narrow lumen. Some areas showed internal hemorrhage, while the malignant cells did not appeared in the kidney (Fig. 9).

Liver: Control animals showed the normal structure of liver. The liver architecture formed from polygonal lobules. The outlines of the lobules were indistinct. The hepatocytes were arranged in cords that radiated out from the center of each lobule where the central vein situated. The hepatocytes were polyhedral in shape, had vesicular spherical nuclei with prominent nucleoli and eosinophilic cytoplasm. Between these hepatic cords were the hepatic sinusoids (Fig.8). The portal area appeared normal and contained portal vein, hepatic artery and branch of bile duct.

Fig.7. Photomicrograph of kidney of a control mouse showing prominent glomerular space (arrow), proximal convoluted tubules (pr), distal convoluted tubules (dc) and collecting tubule (c). H&E   X 200.

Fig.8. Photomicrograph of liver of a control mouse showing normal hepatic lobule, central vein (v), hepatic cords (arrow) and hepatic artery (HA).   H&E   X 200.

Fig.9. Photomicrograph of kidney of a mouse injected subcutaneously with EAC cells, showing: cloudy swelling (c), congested renal corpuscles with closed or very narrow glomerular space (arrow) and internal renal hemorrhage (h).   H&E   X 200.
Liver: The histological structure of the liver showed lymphocytic cells invaded the liver tissue. The portal vein showed congestion and edema with invaded leucocytes with mononuclear cells. The hepatocytes showed degenerative changes as vacuolar degeneration and pyknosis. The hepatic cords as well as the hepatic sinusoids were indistinct (Fig. 10).

Group III: Mice injected subcutaneously with EAC cells, then after one week injected with Ag18 extract.

Kidney: The histological structure of the kidney still showed cloudy swelling of the renal tubules. The renal corpuscles appeared less congested with clear glomerular space. Both proximal and distal convoluted tubules showed prominent lumen, while the brush border of proximal tubules did not appeared (Fig. 11).

Liver: The histological structure of the liver showed that the lymphocytic cells appeared as fragments of different sizes and were presented toward the central vein. The congestion was decreased and the hepatocytes showed less degenerative changes and were resemble to normal structure. The hepatic cords as well as the hepatic sinusoids were distinct (Fig. 12).

Group IV: Mice injected subcutaneously with EAC cells, then after one week injected with Ag20 extract.

Kidney: The histological structure of the kidney showed that the epithelia of the renal tubules appeared with few cloudy swelling. The renal corpuscles appeared with a decrease in congestion with clear glomerular space. Both proximal and distal convoluted tubules showed intact cells with prominent lumen, and the brush border of proximal tubules was obvious (Fig. 13).

Liver: The histological structure of the liver showed that the lymphocytic cells were greatly reduced in number and presented mainly in portal area. The hepatocytes in the central zone of hepatic lobule showed great improvement and appeared as normal. While the hepatocytes at the peripheral zone of hepatic lobule still showed cloudy swelling and degenerative changes. The architecture of hepatic cords appeared normal (Fig. 14).
A very highly significant reduction in tumor volume was observed during experimentation in the treated mice compared to tumor untreated group (table3). The (Ag18 & Ag20) Streptomyces extract administration reduced tumor volume indicating inhibition in the growth and multiplication of tumor cells which may be due to the decrease in the ascites fluid acting as a direct nutritional source or the presence of compounds inhibiting mitosis, DNA synthesis or replication via enzyme pathways. This finding is concomitance with Banu et al., (2011).

The histological structure of kidney of mice injected subcutaneously with EAC cells showed degenerative changes as cloudy swelling of the renal tubules. Also renal corpuscles appeared congested. Some areas showed internal hemorrhage. The same changes were observed by (Holdaas, et al., 1985) and (Abd El-Wahab and Fouda, 2009), who concluded that, the congestion and areas of interstitial haemorrhage may lie in the weakness of the renal parenchymal tissue as a result of the degenerative changes. These structural changes reflect upon one or more of the principal functions of the kidneys, which include volume regulation, acid base balance, electrolyte balance, excretion of waste products and endocrine functions including the elaboration of rennin and erythropoietin (Cotran, 1987).The histological structure of kidney of mice injected subcutaneously with EAC cells showed degenerative changes.

The histological structure of the liver showed lymphocytic cells invaded the liver tissue. The portal vein showed congestion and edema with invaded leucocytes with mononuclear cells. The hepatocytes showed degenerative changes as vacuolar degeneration and pyknosis. The hepatic cords as well as the hepatic sinusoids were indistinct. The same degenerative changes were reported by (Fouda, 2005; Bhattacharyya, et al., 2007 and Chakraborty, et al., 2007; Abd El-Wahab and Fouda, 2009). This may be due to the accumulation of haemorrhagic ascetic fluid within the peritoneal cavity in which the cells proliferate and move to invade the internal organs (Chakraborty, et al., 2007).

The histological picture of both kidney and liver of mice injected with EAC cells, then after one week injected with Ag18 or Ag20 showed less degenerative changes and decreased congestion. The cells were appeared resemble to normal structure. The same results were mentioned by (Fouda, 2005; Abd El-Wahab and Fouda, 2009) using tetradoxin as antitumor.

A reliable criterion for judging the value of any anticanceragents is the prolongation of life span of animals (Hogland, 1982). A decrease of degenerative changes in both kidney and liver in vivo as well as decrease of viable tumor cell count in vitro, as mentioned above, reduced the tumor cells and increase the life span of EAC tumor bearing mice.

4 Discussion

The present study was carried out to evaluate the antitumor activity of metabolites from Streptomyces on EAC tumor bearing mice. Two isolates of Streptomyces extracts were obtained and used as antitumor agent against EAC. PCR amplification of fragments from Streptomyces isolates, indicating their potential for production of polyketide secondary metabolites (Izumikawa et al., 2006). Busti et al., (2006) stated that, since PKS type I genes encode modular enzymes, and actinomycete strains usually contain more than one PKS gene cluster, it was expected that PCR products obtained with the KS-specific primers would represent mixtures of the KS-coding sequences. Therefore, sequencing of these gene fragments would be required for a better understanding of the diversity within the selected group of isolates and their dereplication.

Ascites fluid is the direct nutritional source for tumor cells. So, a rapid increase in ascites fluid with tumor growth would be a mean to meet the nutritional requirement of tumor cells (Rajeshwar et al., 2005).

The EAC cells treated with Ag18 and Ag20 in vitro in this study appeared coloured with trypan blue. The blue colouration indicates to rupture of EAC cells membranes and the trypan blue pass through the broken membranes into the inside of cells. Thus we can suggest that the Streptomyces extracts (Ag18 & Ag20) inhibited the EAC cell growth. This is greatly supported by the significant decrease in the number of viable cells and increase in dead cell population. Similar results have been reported (Gurkan et al., 1988; Prerona et al., 2011).

The mice body weights recorded very highly significant change as found in (table 2). This is in agreement with Altun and Ozalpan (2004); who proved that the inoculation of EAC cells into mice caused significant increase in the mice body weight after one month of inoculation. Such increase was due to accumulated ascites fluid of EAC in peritoneal cavity.
In conclusion, the present study showed that the Streptomyces extracts (Ag18 & Ag20) reduced the tumor cells and increased the life span of EAC tumor bearing mice. These suggest that Streptomyces extracts (Ag18 & Ag20) exhibits potential antitumor activities.
